Enough in total. One group empty.

A saved Psephos attendance experiment. The five groups, finite population, equal request and uniform-sampling rule are modern assumptions, not recovered daily turnout or a historical jury quota.

Current counts

	Current attendance
Present in total	10 of 20
Requested places	10 (2 per group)
Complete rows available	2
Groups below the request	0

Every group meets the request.

2 full five-person rows are possible in this teaching constraint. The historical text does not tell us what officials did with an uneven daily turnout. This result is not a claim that an ancient court was cancelled.

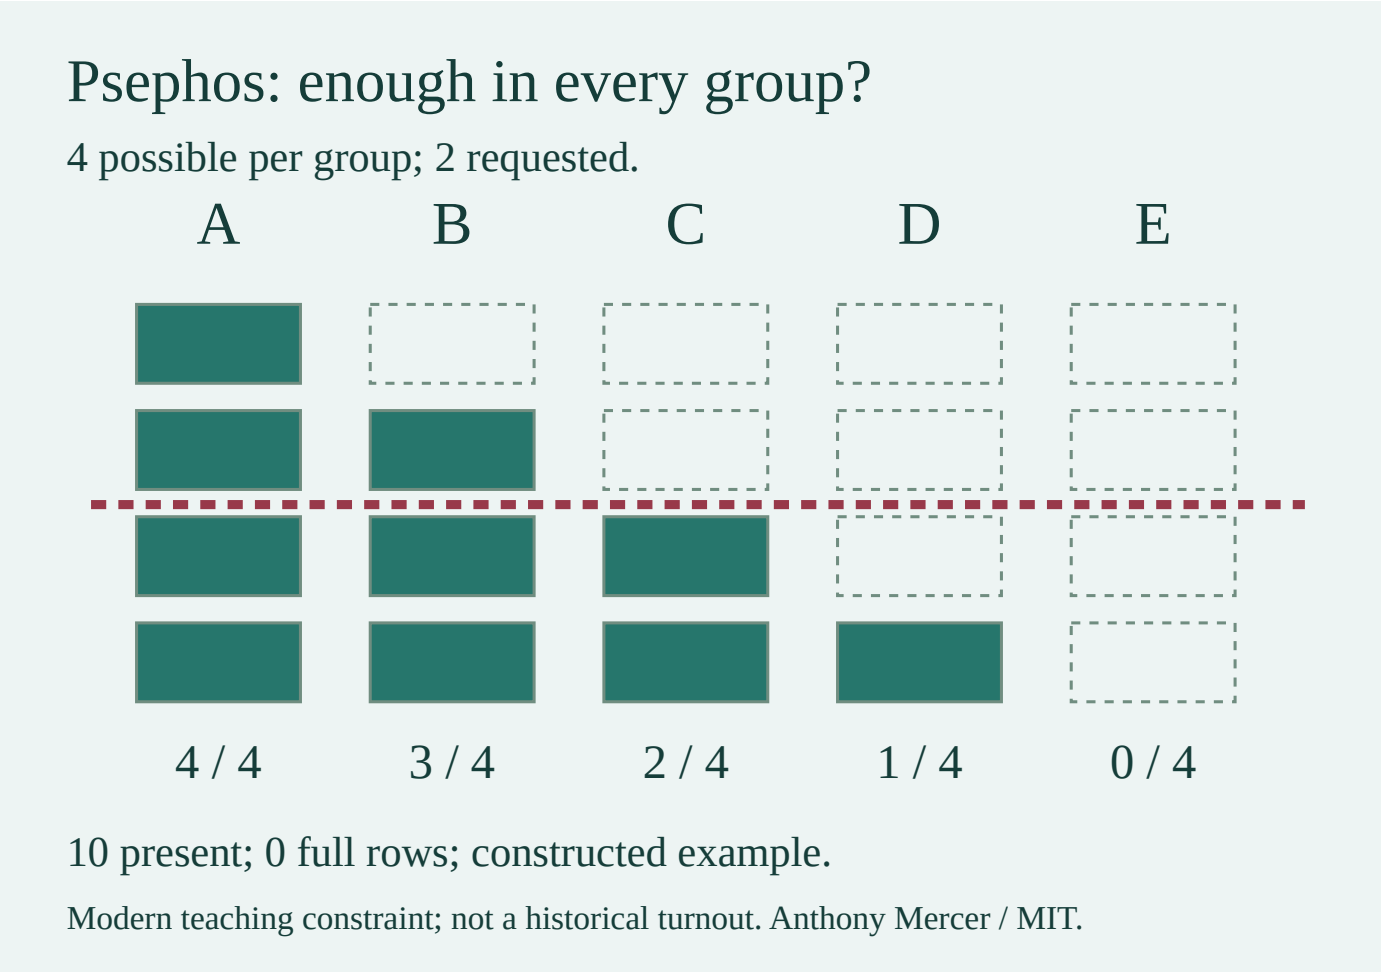

This attendance is recorded as **constructed**. Its counts are 2–2–2–2–2, using the modern group tags A–E.

Keep the comparison

Kept attendance

Counts 4–3–2–1–0; total 10. A group is short.

▼ Inspect kept counts and assumptions

4 possible per group, 2 requested; recorded as constructed.

The population, request and total are the same. Different distributions can change whether every group meets the request; a uniform-sample probability at that total stays the same.

Your explanation

The same ten fill two rows only when each group has two. <Counts are known>; the 4.21% concerns a new uniform sample, not doubt about this board. παραπλησίως ἴσοι.

A chance for an unknown sample

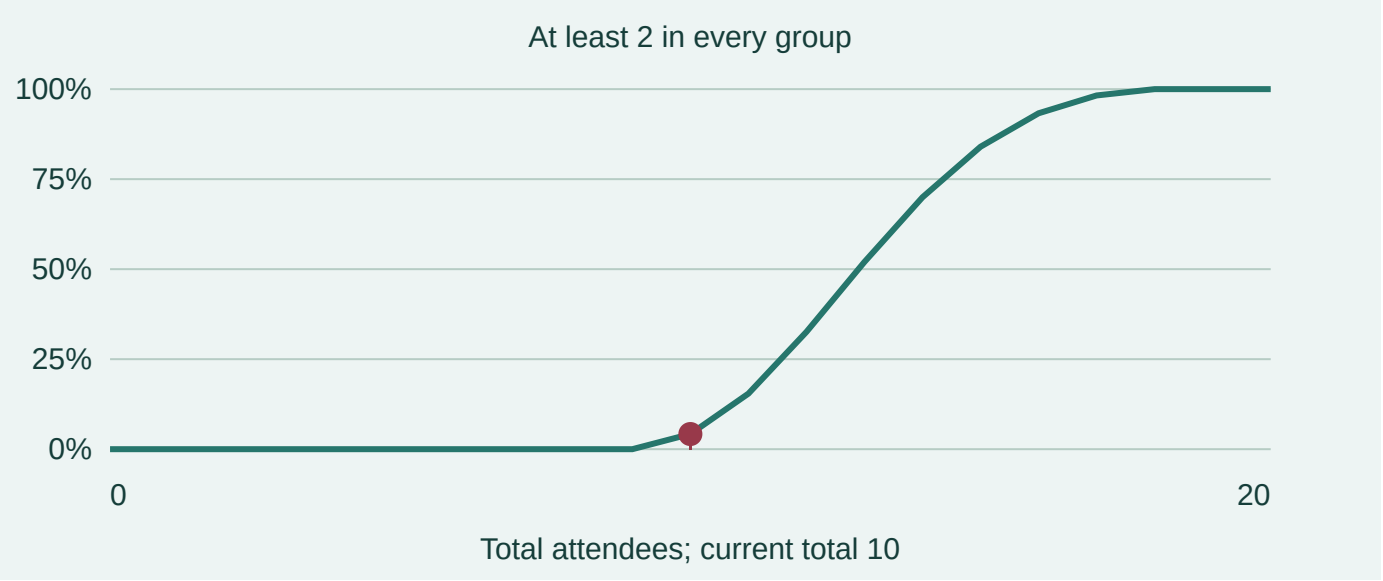

Assume every subset of **10** distinct people from these 20 possible people is equally likely. What fraction has at least 2 in every group?

7,776 / 184,756 ≈ 4.21%

Reduced exact fraction: 1944/46189. These are counts of individual subsets, not equally weighted count patterns.

The displayed pattern 2–2–2–2–2 represents **7,776** of those 184,756 subsets. Its present counts already determine whether it meets the request. The probability above concerns an *unknown new sample* of that same size.

At least 10 total is necessary. A total of **18** guarantees the per-group request within this finite model, however the arrivals are distributed: fewer can leave one group short. This guarantee is a mathematical bound, not a proposed historical attendance rule.

Exact model for every possible total

Present	Favourable subsets	All subsets	Exact chance
0	0	1	0/1
1	0	20	0/1
2	0	190	0/1
3	0	1,140	0/1
4	0	4,845	0/1
5	0	15,504	0/1
6	0	38,760	0/1

Present	Favourable subsets	All subsets	Exact chance
7	0	77,520	0/1
8	0	125,970	0/1
9	0	167,960	0/1
10	7,776	184,756	1944/46189
11	25,920	167,960	648/4199
12	41,040	125,970	72/221
13	40,320	77,520	168/323
14	27,120	38,760	226/323
15	13,024	15,504	814/969
16	4,520	4,845	904/969
17	1,120	1,140	56/57
18	190	190	1/1
19	20	20	1/1
20	1	1	1/1

The Greek and its limits

Letters within a tribe (63.4)

καὶ γράμμα ἓν τῶν στοιχείων μέχρι τοῦ κ· νενέμηνται γὰρ κατὰ φυλὰς δέκα μέρη οἱ δικασταί, παραπλησίως ἴσοι ἐν ἑκάστῳ τῷ γράμματι.

And one letter of the alphabet up to kappa; for the jurors have been divided, tribe by tribe, into ten parts, approximately equal in number under each letter.

This continues the description of a boxwood ticket carrying the man's own name, his father's name and deme. The letter groups are within each tribe. A–E are modern tags for five of its ten groups, not transcriptions of the Greek letters or names of five tribes. The numbered identities are invented.

γράμμα (grámma)
A letter. Here it labels a group of tickets, rather than a verdict or a named courtroom.

κατὰ φυλὰς (katà phulàs)
Tribe by tribe. This phrase prevents us from treating the five displayed letter groups as five tribes.

παραπλησίως ἴσοι (paraplēsíōs ísoi)
Approximately equal. The teaching board's completely filled equal columns are an additional simplifying assumption.

Who puts the tickets in? (64.2)

[κληροῦται δ᾽] οὗτος, ἵνα μὴ ἀεὶ ὁ αὐτὸς ἐμπηγνύων κακουργῇ. εἰσὶ δὲ κανονίδες [πέντε ἐ]ν ἑκάστῳ τῶν κληρωτηρίων.

This man [is chosen by lot], so that the same person should not always do wrong while inserting the tickets. There are [five] ticket frames in each allotment device.

The preceding lines call him the empēktēs and match a ticket's letter to its column's letter. Brackets retain Kenyon's supplied text, including [πέντε ἐ] where the supply crosses a word boundary. Translating klērōtērion as a device follows the material interpretation; older translations used 'balloting-room'. Letting you swap two tickets is a modern experiment, not a prescribed historical action.

ἐμπηγνύων (empēgnúōn)
While inserting. The person handling the physical ticket placement is part of the procedure's safeguards.

ἵνα μὴ (hína mḕ)
So that not: a purpose clause. It gives the reason for choosing the inserter by lot, without proving cheating was impossible.

κανονίδες (kanonídes)
Frames or strips that hold tickets. They are represented as vertical columns in the schematic.

κληρωτηρίων (klērōtēríōn)
Of allotment devices, the genitive plural. A klêros is a lot.

One white cube, five tickets (64.3, first part)

εἰσὶ δὲ κύβοι χαλκοῖ, μέλανες καὶ λευκοί. ὅσους δ᾽ ἂν δέ[ῃ λαχεῖν] δικαστάς, τοσοῦτοι ἐμβάλλονται λευκοί, κατὰ πέντε πινάκια εἷς, οἱ δὲ μέλανες τὸν αὐτὸν τρόπον.

The cubes are bronze, black and white. According to how many jurors are needed [to be selected], white cubes are put in, one for every five tickets; the black ones in the same way.

The grouping and quota come from the text. Applying successive cubes to successive horizontal rows is the usual material interpretation, represented here by an abstract

release lane. The four-, six- or eight-row board, a uniform random colour order and complete rows are explicit modern assumptions. Cube form and release hardware are not reconstructed.

κύβοι (kúboi)
Cubes. These are black/white selection lots, not numbered gaming dice or the pierced/solid verdict ballots.

χαλκοῖ (khalkoî)
Bronze; the text identifies a material. White and black refer to the two kinds of lot.

κατὰ πέντε πινάκια εἷς (katà pénte pinákia heîs)
One for every five tickets. One draw can decide a whole five-ticket row, rather than a separate coin toss per person.

The inserter also counts (64.3, final sentence)

ὑπάρχει δὲ καὶ ὁ ἐμπήκτης εἰς τὸν [ἀριθμό]ν.

The ticket inserter is also included in the [number].

This is an important exception to a simple story in which every participant waits on a row. The inserter has already been chosen by lot. Our probability calculations cover only the ordinary tickets on the teaching board; they neither assign him a row chance nor compute the total historical jury quota. Kenyon brackets ἀριθμό, leaving the final ν outside.

ἐμπήκτης (empḗktēs)
Ticket inserter, the official role named in 64.2. The word describes his work, not another kind of cube.

καὶ (kaì)
Also. Omitting this short sentence would erase a person whom the text counts.

Selected for service is not assigned to a court (64.4, purpose clause)

ἵν᾽ εἰς οἷον ἂν λάχῃ εἰσίῃ καὶ μὴ εἰς [οἷο]ν ἂν [βούλ]ηται, μηδ᾽ ᾖ συναγαγεῖν [εἰς] δικαστήριον οὓς ἂν βούληταί τις.

So that he enters whichever court he receives by lot, rather than whichever he wishes, and so that no one can assemble in a court the men he wishes.

The preceding lines describe drawing a lettered balanos and putting the selected man's ticket in its matching court box. That later allotment is outside this bench. 'Both selected' below means both enter the service pool, not both hear the same case. The English supplies 'court' from the context.

λάχῃ (lákhēi)
Receives by lot; a form of lankhánō. Selection and later court assignment are distinct stages.

δικαστήριον (dikastḗrion)

A court. A row's letter groups do not name the courts to which the selected men will go.

βούληται τις (boúlētaí tis)
Someone wishes. The clause states a purpose of the procedure, not a measured guarantee of resistance to every manipulation.

The registered groups in 63.4 are approximately equal; this does not determine who arrives on a given day. The smallest represented group limits complete rows in this teaching model. We do not infer a historical response to uneven attendance. The ticket inserter, total ancient jury quota and later courtroom assignment are outside these calculations.

Research reference: David C. Mirhady and Carl Schwarz, “Dikastic Participation”, *Classical Quarterly* 61.2 (2011), 753–757, doi:10.1017/S0009838811000176. Their random-arrival study motivates the question; this is a smaller exact model. The article is an external reference, not an embedded asset.

Complete primary witnesses

Kenyon’s edition first published 1920; the scanned imprint lists reprints through 1958. Leaf 77 and leaf 78 both print LXIV. The heading and archive leaf are retained separately. Source images, fonts and notices were checked against their retained SHA-256 identities before this reading was made.
